Cheat Sheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example
	^	Example:
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	 1. 1 2. 2 dict_name = {} #Creates an empty dictionary person = { "name": "John", "age": 30, "city": "New York"}
Accessing Values	You can access the values in a dictionary using their corresponding keys.	Copied! Syntax:
		<pre>1. 1 1. Value = dict_name["key_name"] Copied!</pre>
		Example:
		1. 1 2. 2
		1. name = person["name"] 2. age = person["age"]
		Copied! Syntax:
	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	 1. 1 1. dict_name[key] = value
		Copied!
Add or modify		Example:
		1. 1 2. 2
		<pre>1. person["Country"] = "USA" # A new entry will be created. 2. person["city"] = "Chicago" # Update the existing value for the same key</pre>
del	Removes the specified key-value pair from the dictionary. Raises a KeyError if the key does not exist.	Copied! Syntax:
		1. 1
		1. del dict_name[key] Copied!
		Example:
		1. 1
		<pre>1. del person["Country"]</pre>
		Copied! Syntax:
		1. 1
		1. dict_name.update({key: value})
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.	Example:
	pano.	1. 1
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	<pre>1. person.update({"Profession": "Doctor"})</pre>
		Copied! Syntax:
		1. 1
		1. dict_name.clear()
		Copied!
		Example: 1. 1
		1. grades.clear()

about:blank 1/4

about:blank

Copied! Example: 1. 1 You can check for the existence of a key in a dictionary key existence using the in keyword if "name" in person: print("Name exists in the dictionary.") Copied! Syntax: 1. new_dict = dict_name.copy() Copied! Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the copy() Example: original, but they remain distinct objects in memory. 1. new_person = person.copy() 2. new_person = dict(person) # another way to create a copy of dictionary Copied! Syntax: 1. 1 1. keys_list = list(dict_name.keys()) Retrieves all keys from the dictionary and converts them Copied! into a list. Useful for iterating or processing keys using keys() list methods. Example: 1. person_keys = list(person.keys()) Copied! Syntax: 1. 1 1. values_list = list(dict_name.values()) Extracts all values from the dictionary and converts them Copied! into a list. This list can be used for further processing or values() analysis. Example: 1. 1 1. person_values = list(person.values()) Copied! Syntax: 1. 1 1. items_list = list(dict_name.items()) Retrieves all key-value pairs as tuples and converts them Copied! into a list of tuples. Each tuple consists of a key and its items() Example: corresponding value. 1. 1 1. info = list(person.items()) Copied!

Sets

Package/Metho	d Description	Code Example
		Syntax:
		1. 1
add() clear()	Elements can be added to a set using the 'add()' method. Duplicates are automatically removed, as sets only store unique values. The 'clear()' method removes all elements from the set, resulting in an empty set. It updates the set in-place.	<pre>1. set_name.add(element)</pre>
		Copied!
		Example:
		1. 1
		 fruits.add("mango")
		Copied!
		Syntax:
		1. 1
		<pre>1. set_name.clear()</pre>

10/13/24, 7:51 PM about:blank

```
Copied!
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. fruits.clear()
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. 1
                                                                                                             1. new set = set name.copv()
                                                                                                           Copied!
                  The 'copy()' method creates a shallow copy of the set. Any modifications to the copy
copy()
                  won't affect the original set.
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. new_fruits = fruits.copy()
                                                                                                           Copied!
                                                                                                          Example:
                                                                                                             2. 2
                  A set is an unordered collection of unique elements. Sets are enclosed in curly braces
Defining Sets
                   `{}`. They are useful for storing distinct values and performing set operations.
                                                                                                             1. empty_set = set() #Creating an Empty
2. Set fruits = {"apple", "banana", "orange"}
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. 1

    set_name.discard(element)

                                                                                                           Copied!
                  Use the 'discard()' method to remove a specific element from the set. Ignores if the
discard()
                  element is not found.
                                                                                                          Example:

    fruits.discard("apple")

                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. is_subset = set1.issubset(set2)
                                                                                                           Copied!
                  The 'issubset()' method checks if the current set is a subset of another set. It returns
issubset()
                  True if all elements of the current set are present in the other set, otherwise False.
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. is_subset = fruits.issubset(colors)
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                          is superset = set1.issuperset(set2)
                  The 'issuperset()' method checks if the current set is a superset of another set. It
                                                                                                          Example:
issuperset()
                  returns True if all elements of the other set are present in the current set, otherwise
                  False.
                                                                                                             1. 1
                                                                                                             1. is_superset = colors.issuperset(fruits)
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. removed_element = set_name.pop()
                                                                                                           Copied!
                  The 'pop()' method removes and returns an arbitrary element from the set. It raises a
                   'KeyError' if the set is empty. Use this method to remove elements when the order
pop()
                                                                                                          Example:
                  doesn't matter.
                                                                                                             1. removed_fruit = fruits.pop()
                                                                                                           Copied!
                  Use the 'remove()' method to remove a specific element from the set. Raises a
remove()
                                                                                                           Syntax:
                   'KeyError' if the element is not found.
                                                                                                             1. 1
                                                                                                             1. set_name.remove(element)
                                                                                                           Copied!
```

10/13/24, 7:51 PM about:blank

Perform various operations on sets: 'union', 'intersection', 'difference', 'symmetric

The 'update()' method adds elements from another iterable into the set. It maintains

Example:

- 1. 1
- fruits.remove("banana")

Copied!

Syntax:

- 1. 1 2. 2 3. 3 4. 4

- 1. union_set = set1.union(set2)
 2. intersection_set = set1.intersection(set2)
 3. difference_set = set1.difference(set2)
 4. sym_diff_set = set1.symmetric_difference(set2)

Copied!

Example:

- 1. 1 2. 2 3. 3 4. 4
- 1. combined = fruits.union(colors)
- 2. common = fruits.intersection(colors)
- 3. unique_to_fruits = fruits.difference(colors)4. sym_diff = fruits.symmetric_difference(colors)

Copied!

Syntax:

- 1. 1
- set_name.update(iterable)

Copied!

Example:

1. fruits.update(["kiwi", "grape"])

Copied!

the uniqueness of elements.
